Jupiter

Main invisible nucleus of Jupiter is covered by giant clouds (visible atmosphere). Visible atmosphere is surrounded by giant invisible outer atmosphere (H, He). The outer atmosphere consists by light particles mainly. The light particles are in the stellar wind that are capturing by gravitation of the giants. The thick clouds are strong evidence about a very fiery planet. Huge anti-cyclone is the red spot and is formed by three atmospheric streams; there is huge pressure on the planet's invisible main nucleus, approximately 1000-1500 atmospheres.

Fiery gaseous streams from surface are moving rapidly to the upper layers of visible atmosphere. Fiery gaseous admixtures are cooling and light admixtures can penetrate within the upper layers. Jupiter has very moving inner clouds. The clouds create a lot of zone of high pressure belts in between for chemical snowing, raining and evaporation. Deep atmosphere of a giant is gaseous diffuser which sorts atoms by mass and chemical admixtures by density. Each admixture into a giant atmosphere has own main zone of circulation (changing of aggregation states). Circulation enormous admixtures form a lot of deep zones of thick clouds: spots, cyclones, anticyclones, "curious" clouds. Of course surface of the inner atmosphere has abundance of light admixtures. Lighter admixtures have more chance to penetrate within upper layers. The hot chemical crystals within upward chemical streams become cold. Hit between few streams produce well known red spot. The rest parts of clouds avoid red spot and without changing aggregation condition continues its movement around

the Jupiter. Without atmosphere diameter of the Jupiter is approximately 88000 km. Scientists decided that invisible nucleus of the Jupiter (D 88000km) is nucleus of solid (metallic) hydrogen.

When we know laws of universe we can explain everything. False Jupiter of the NASA is very interesting. In the middle is solid layer of the hydrogen $T \approx -260^{\circ}\text{C}$.

1. At the red-hot nucleus ($+30000^{\circ}\text{C}$) is solid layer of the hydrogen $T \approx -260^{\circ}\text{C}$. ???... Unbelievable False!

2. Within visible atmosphere between -150°C and -260°C ... are huge circulation of inner atmosphere streams???... Unbelievable False! ...Into such diapason only few chemical elements can be circulated. But we can see colors of almost all gaseous chemical admixtures. Spacecraft discovered on the visible surface "warm" vortex??? Where did they come from?

3. 90% mass of Jupiter is Hydrogen and Helium???... Unbelievable False!

The atmosphere thickness on the equator is approximately 27500 km. Aggregation changing between atmosphere layers of light admixtures produces chemical snowing and chemical raining within high pressure belts and could not reach the surface of the invisible nucleus. H_2O as well as other chemical admixtures has own thermal circulation zone. Circulating within own zone it can change liquid, gasses and solid conditions. There is a colossal atmosphere pressure on the fiery ($\sim 1500^{\circ}\text{C}$) surface of planet. In these conditions main masses of H_2O and other admixtures almost can't penetrate onto surface of the main invisible nucleus as well as to the visible surface. Thus multi-stage separated atmosphere layers of the Jupiter are simply fantastic and unbelievable for the modern knowledge.
